TITLE The Equivalence Scheme of a Semiconductor Triode at High
Frequencies.
PERIODICAL Radiotekhnika, 11, fasc. 10, 25-29 (1956)
Issued: 11 / 1956

The task of determining the equivalence scheme of a semiconductor triode leads to the production of an electromodel which is able to reproduce the transition process with sufficient accuracy. Such methods have already been suggested first by FORLEY and later by SHEA, where the latter is the more accurate method, but both have disadvantages, as the analysis of even the most simple tasks was rendered considerably more complicated. The present work tries on the one hand to find a scheme which takes the particular properties of the transition characteristic into account with sufficient accuracy, and on the other, is relatively simple for purposes of analysis.

In the following the construction of such a scheme is demonstrated, on which occasion not the approximated expression, but the curve easily obtained by direct experimental determination with the help of experimental impulses is approximated. The parameters of the approximation function are then determined from the frequency characteristic of the semiconductor triode in accordance with formulae given here. The formulae which are eventually obtained show that the transition- and thus also the frequency characteristic

TITLE: Effect of Operating Conditions of a Triode Transistor
on Frequency Characteristics and Pulse Rise Time
(Vliyaniye
zavisimosti chastotnykh svoystv poluprovodnikovogo trioda
ot yego elektricheskogo rezhima na dlitel'nost' frontov)

PERIODICAL: Radiotekhnika, 1958, Vol. 13, Nr 2, pp. 54 - 58 (USSR)
Received: April 25, 1958

ABSTRACT: The influence of the dependence of frequency properties
of a semiconductor triode on the mode of electric opera-
tion of the latter on the step rise duration generated
with a reactance in relaxation self-excited alternating
current generator is investigated here. On the strength
of the graphical-analytical analysis given here the fol-
lowing is determined: 1) The dependence of the frequency
properties of the semiconductor triode on the mode of electric
operation of the latter leads to a prolongation of the
step rise duration. 2) The influence of the mentioned de-

Card 1/3

SOV/108-13-2-9/15

Effect of Operating Conditions of a Triode Transistor on
Frequency Characteristics and Pulse Rise Time

pendence on the step rise duration is comparatively weak.
This influence is the weaker, the smaller the ratio (4)

$$(U_K^* - U_{K_{\min}}) / (U_{K_{\max}} - U_{K_{\min}}) \text{ is.}$$

(here = 0,4). 3) If the ratio (4) does not exceed 0,3-0,4
the modification of the frequency properties can be neglect-
ed in the computation of the front under taking into ac-
count of the real character of the $k = f(U_K)$ curve. 4) The
influence of the alteration of the frequency properties in
the semiconductor triode on the duration of trailing edge
is considerably greater. However, also in this case its
influence is the weaker, the smaller the ratio (4) is.
5) The ratio (4) depends on the properties of the triode
itself (U_K^*) as well as on the scheme type and on the para-
meter values of the scheme ($U_{K_{\min}}, U_{K_{\max}}$). The most con-

venient method for the reduction of the ratio (4) is an
increase of $U_{K_{\max}}$. This can be obtained by the selection
of a rational circuit for the relaxation self-excited alter-

Card 2/3

SOV/108-13-2-9/15

*Effect of Operating Conditions of a Triode Transistor on Frequency
Characteristics and Pulse Rise Time*

nating current generator (e.g. the circuit with a collector-dipole yields the smallest $U_{K_{max}}$ value under equal conditions), and by a corresponding selection of the circuit parameters. In most cases this will be obtained by the reduction of R_B and R_K and increase of E_K . From this point of view it is expedient to choose triodes with a small $U_{K_{max}}^*$.

Thus the dependence of the frequency properties on the mode of electric operation observed in the semiconductor triodes leads in a series of cases to the stretching of the trailing edge of the generated pulse. By a rational selection of the circuit and its parameters, however, the influence of the mentioned nonlinearity can be reduced to a minimum. There are 5 figures and 6 references, 2 of which are Soviet.

TITLE: Aerosol and cloud study facilities at Obninsk (USSR)

SOURCE: Znaniye - sila, no. 3, 1966, 10-11

TOPIC TAGS: micrometeorology, aerosol, cloud physics, fog, atmospheric cloud

ABSTRACT: The Aerosol Laboratory of the Institute of Applied Geophysics (Main Administration of the Hydrometeorological Service, Soviet of Ministers USSR), which is located at Obninsk, site of the 300-m meteorological tower, consists of a large vertical cloud chamber and several special wind tunnels. The cloud chamber is as high as a five-story building and has five interior balconies. Instruments can be installed at any point inside the chamber. All machinery and pipeline valves can be controlled from a central control console which also contains all signalling facilities and recorders for registering instrument readings. The 3200-m³ chamber can be filled with dense fog (steam) in 2-3 min.

Icing phenomena can be studied in a special horizontal wind tunnel. Air is forced through its 80-cm working section at about 300 km/hr by a 400-kw motor at a rate of 150,000 m³/hr.

Two five-story, 100-m³, double-walled, cylindrical, thermobaric chambers are available for studies of vertical currents. Coolant is circulated between the walls, the outsides of the chambers are insulated, and the facility is equipped with vacuum pumps, making it possible to achieve a pressure of 0.04 atm and a temperature of -45°C within the chambers. Consequently, clouds can be forced to rise from a simulated height of 5.5 km to their maximum height of existence, ascending and descending currents can be set up, clouds can be evacuated from the chambers, and the chambers can be filled with fresh air or "new" clouds. The chambers are now being used to study supercooled clouds.

A 50-m vertical wind tunnel was installed to facilitate studies of raindrop formation and rain clouds. The first story below the actual wind tunnel is a hermetically sealed chamber shaped like an old radio loudspeaker whose small end is the entrance to the wind tunnel. Aerosols, dust particles, water droplets, or a combination can be introduced simultaneously through jets at the entrance; then they pass through the working section at relatively low speeds. Instruments can be installed at any point inside the wind tunnel, which is equipped with large observation window, by special manipulators regulated from a central console. Orig. art. has: 3 figures.

TITLE: On the distribution function of liquid precipitation particles. (O funktsii raspredeleniya chastits zhidkikh osadkov).

PERIODICAL: "Izvestiya Akademii Nauk, Seriya Geofizicheskaya"
(Bulletin of the Ac.Sc., Geophysics Series), 1957, No.6,
pp. 838-839 (U.S.S.R.)

ABSTRACT: Litvinov, I.V. (1) has found that a spectral distribution of the rain droplets formed by the thawing of the solid particles with various degrees of grain distribution is not described adequately by the distribution functions of Marshall-Palmer, Best and by the logarithmic normal functions. Litvinov proposes a distribution function which describes better the spectral distribution of rain of various types, namely:

$$\rho = N \ell^{-\lambda d^{3/2}}, \quad (1)$$

where ρ is the distribution density of droplets of the dia d , N and λ are the power functions of the precipitation intensity, whereby the constants of the power functions differ for rains of various types. Additional calculations indicate that the distribution of various rains

Card 1/2

49-6-21/21

On the distribution function of liquid precipitation particles. (Cont.)

are also satisfactorily described by a function described by Polyakova, Ye. A. and Shifrin, K. S. (2), namely:

$$\rho = Ad^2 \ell^{-\gamma d}, \quad (2)$$

where A and γ are functions of the precipitation intensity. The graphs, Fig.1-3, indicate results of verification as to what extent the function of the latter mentioned authors satisfy measured data of the distribution for rains of various types. It was found that in addition to the function, eq.(1), the distribution function, eq.(2), can also be utilised.

SOV/49-58-7-8/16

TITLE: Spectral Distribution of Raindrops Produced from Thawing Hail (Spektral'noye raspredeleniye kapel' v dozhdyakh, obrazovannykh tayaniyem grada)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya, 1958, pp 903 - 912 (USSR)

ABSTRACT: The measurements were carried out of the spectral distribution of the rain produced from thawing hail. It was observed that this type of rain has a special character. Several typical rainfalls were chosen for a detailed analysis. Their intensities are shown in Figure 1a, where the co-ordinates represent the time (t) at the intervals of 15 min and the amount of rain (l) in mm. It may be noted that the frequency of the larger raindrops was always higher at the beginning of the fall. The spectral distribution of the rainfalls is shown in Figure 2 (representing a selection of 135 spectra), the co-ordinates giving the drop diameter and the log of their distribution. It can be seen that the experimentally prepared graphs agree fairly well with the Marshall-Palmer's function of the diameter distribution (7).

Card 1/4

SOV/49-58-7-8/16

Spectral Distribution of Raindrops Produced from Thawing Hail

The spectral distribution is seen in Figure 3. This again can be shown as a Best's function (8) where F - water amount in a drop, a , n - constants. The above two functions can be combined, giving a curve (Figure 4). In order to verify the spectral distribution, the function (9) was applied. The data was tabulated (Table 1) and given in a form of graphs (Figure 5), showing clearly the distribution of the raindrop size. Similarly, the function (10) is represented by Figure 6 in order to show an uneven distribution of the drop diameter. This uneven distribution can be seen on most of the curves as a definite minimum at the drop diameter $d = 1.75 \pm 0.25$ cm (Figure 7). It was difficult to explain this phenomenon without further experimentation. Therefore, a special apparatus was designed (Figure 8) by means of which a spray of water could be separated from the larger drops of thawing hail. The spectral distribution curve of the spray showed the minimum at $d = 1.05$ mm with the largest drop diameter about 1.6 mm.

Consequently, it was assumed that the spectral distribution of the rain, as carried out previously, was the result of

Card2/4

SOV/49-58-7-8/10

Spectral Distribution of Raindrops Produced from Thawing Hail

the superimposing of two different distributions: the spectral distribution caused by the nucleus of the thawing hail and the spectral distribution of water spray blown off the thawing hail granules.

A third possibility should also be considered. When the freezing level in the atmosphere is situated above the lower saturation surface, the falling hail will attract the cloud drops, which would not freeze due to the higher temperature of the surroundings. These drops will also show a minimum on the spectral distribution curve. Thus, a feature of the minimum formed in the centre of the spectral distribution curve can be considered as a sign by which the rain can be recognised as being of hail origin. There are 9 figures, 2 tables and 14 references, 6 of which are Soviet and 8 English.

AUTHOR: Litvinov, I.V.TITLE: On the Origin of Multilayer Hail (O pristoydenii mnogosloynykh gradin)

PERIODICAL: Izvestija Akademii Nauk SSSR, Seriya Geofizicheskaya, 1953, Nr 2, pp.277-279 (USSR)

ABSTRACT: The author investigates in some detail the causes bringing about formation on hail of transparent as well as non-transparent layers. He found that in the case of high water content formation may take place of a transparent layer when the air temperature reaches low negative values and the cloud does not contain large enough drops. The opaque central core in a multi-layer hail particle is attributed to the fact that for small diameters of a growing basic particle a very high water content in the cloud is required if a transparent layer is to form and the likelihood of this is very small. As was shown by Fraser et alii (Ref.8), the formation of mound shaped ice is possible in the case of high water content of the cloud and this probably explains the observation by Abich of hail with protrusions and mounds. Formation of pear-shaped and plate-shaped hail is possible if the hail falls through a cloud of a high water content. Thereby, a part of the

Card 1/3

49-58-2-16/12

On the Origin of Multilayer Hail.

precipitating water does not freeze immediately after precipitation, gradually scattering and freezing; obviously freezing of the water will take place at the edges of the hail, where heat release is largest and heat supply smallest. The existence of multi-layers is explained by the fact that during its fall the hail intersects regions of the cloud with large or small water contents; during flight through a region with a high water content an increase takes place in the temperature of the hail surface and this brings about the formation of transparent ice, whilst during flight through an area with reduced water contents the temperature of the surface of the hail decreases and opaque ice will form. According to the calculations of K.S.Shishkin, a distance of 100-300 m is required if a layer of 1-2 mm thick is to form and this is in agreement with the diameters of the "bubbles" and "streams" observed during formation of cumulus clouds. Intersection of a "stream" with a

AUTHOR: Litvinov, I. V.

TITLE: A Method of Measuring the Distribution of a Mass of Falling Snowflakes

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geofizicheskaya, 1959, Nr 7, pp 1011-1017 (USSR)

ABSTRACT: The method was elaborated by the El'brus expedition, Academy of Sciences, USSR. It is based on the formula (1) where $q(d)$ - distribution function of the flakes in a plane, $V(d)$ - their velocity, $f(d)$ - distribution of flakes in space (d - equivalent diameter of the water drop produced from a snowflake). The apparatus employed in the measurement is illustrated in Fig 1, showing the source of light 1, 2, 3 which produces a parallel light beam 4. The photographic camera 6 is focussed on the area 5. A photograph 13×18 cm is obtained of the falling snowflakes (Fig 2). Thus, the distribution function $f(a)$ (a - visual flake dimension) can be obtained. The relationship of a and d can be defined as $a = \gamma(d)$ which was determined experimentally by means of another apparatus illustrated in Fig 3. Here, a snowflake passes through two openings, 2, 3 and 4, into a space 5, part of which is lit by the light beam 6. The falling flake, when passing the

Card 1/3

SOV/49-59-7-9/22

A Method of Measuring the Distribution of a Mass of Falling Snow-flakes

photocell 7 , causes the lamp 10 to pulsate. The flake, falling through the space 5 and lit by this pulsating lamp, is photographed several times before it rests on a layer of grease 19 where it melts and the water drops thus produced are photographed again (Fig 4, top - falling flake; bottom - drops of a melted flake. The accuracy of the value γ obtained from photographs, depends on the intensity of precipitation (Eq (2)). This was measured with an apparatus illustrated in Fig 5 where the weight of snow-flakes was recorded on the rotating cylinder 4 . The results of measuring are illustrated in Figs 6-9. Fig 6 shows the relationship of d and a as obtained from the second apparatus, Fig 7 - the relationship of velocity of flakes and the diameter d , Fig 8 - the intensity of precipitation as obtained from the third apparatus and calculated from Eq (2). Fig 9 shows some examples of the flake density ♀

system, a reflector, a measuring photocell, a recording device, and a power supply (see Fig. 1). In order to obtain direct measurements of a certain parameter, in the illuminator circuit is an additional illuminator, the light beam from which is detected by a photoresistor connected through a photocurrent amplifier to the frequency-phase-detector input which, through the power amplifier, maintains a constant rotational speed of the light-beam-modulator's electric motor. AUTHORS: Pastushuk, N.S., Litvinov, L.B., Reznik, M.V., Korsunskiy, M.I.TITLE: The Negative Photoconductivity of Thin Layers of Selenium With
Admixtures of Tellurium

PERIODICAL: Tr. Khar'kovsk. politekhn. in-ta, 1958, Vol 14, pp 111-115

ABSTRACT: The photoconductivity σ of thin layers of amorphous Se with an admixture of Te dusted in vacuum on glass backing at room temperature has been investigated. The darkness conductivity σ_0 of the studied layers is extremely low. It has been shown that the investigated samples have a noticeable negative photoconductivity observed at very weak electric fields (10^{-2} v/cm). The ratio of the dark current to the light current is 1.2-2. The time of establishing the stationary value of σ is equal to 15 - 20 minutes, and the time of relaxation of the "negative" σ , determined from the moment of switching off the light to establishing the equilibrium value, is 12 - 16 hours. It has been pointed out that there is no theory which can explain the described phenomena.

The role of biological factors in forming takyrs along the route of the Turkmen Canal. N. I. Bazilevich, N. M. Gollerbach, M. A. Litvinov, L. E. Rodin, and D. M. Shtellberg. *Bol'sh. Zhur.* 38, 3-30(1953).—A slime membrane of biol. origin (algae) coats mineral particles, reduces evapn., and decreases the upward movement of salts. This in turn encourages more algal growth. The O₂ released in the photosynthetic processes is trapped by the fibers of the algae and when silting takes place a porous structure is formed as the O₂ is forced out or reacts with the medium. With more sediment the porosity is reduced by compaction and a scaly structure ensues. On the surface, cementation causes crust formation, the cementing agents being SiO₂, organo-mineral gels, and carbonates of Ca and Mg. The Na of the incoming waters causes a rise in pH. It has been noted that as the algae develop on the surface after a rain the pH rises to 8.2-8.3.
J. S. Joffe
